<pre>import Global from Global globalObj = Global() print(str(globalObj.Test()))</pre>	

Can you spot the error?

Original code	Human repair
<pre>import Global from Global globalObj = Global() print(str(globalObj.Test()))</pre>	<pre>from Global import Global globalObj = Global() print(str(globalObj.Test()))</pre>

How many repairs could there possibly be?

Consider the following Python snippet, which contains a small syntax error:

```
def prepend(i, k, L=[])  
    n and [prepend(i - 1, k, [b] + L) for b in range(k)]
```

How many repairs could there possibly be?

Consider the following Python snippet, which contains a small syntax error:

```
def prepend(i, k, L=[])  
    n and [prepend(i - 1, k, [b] + L) for b in range(k)]
```

It can be fixed by appending a colon after the function signature, yielding:

```
def prepend(i, k, L=[]):  
    n and [prepend(i - 1, k, [b] + L) for b in range(k)]
```

How many repairs could there possibly be?

```
def prepend(i, k, L=[])  
    n and [prepend(i - 1, k, [b] + L) for b in range(k)]
```

It can be fixed by appending a colon after the function signature, yielding:

```
def prepend(i, k, L=[]):  
    n and [prepend(i - 1, k, [b] + L) for b in range(k)]
```

Let us consider a slightly more ambiguous error: `v = df.iloc(5:, 2:)`. Assuming an alphabet of just a hundred lexical tokens, this statement has millions of two-token edits, yet only six are accepted by the Python parser:

How many repairs could there possibly be?

Consider the following Python snippet, which contains a small syntax error:

```
def prepend(i, k, L=[])  
    n and [prepend(i - 1, k, [b] + L) for b in range(k)]
```

It can be fixed by appending a colon after the function signature, yielding:

```
def prepend(i, k, L=[]):  
    n and [prepend(i - 1, k, [b] + L) for b in range(k)]
```

Let us consider a slightly more ambiguous error: `v = df.iloc[5:, 2:]`. Assuming an alphabet of just a hundred lexical tokens, this statement has millions of two-token edits, yet only six are accepted by the Python parser:

- (1) `v = df.iloc(5:, 2,)`
- (2) `v = df.iloc(5, 2()`
- (3) `v = df.iloc(5[:, 2:]])`
- (4) `v = df.iloc(5:, 2:)])`
- (5) `v = df.iloc[5:, 2:]])`
- (6) `v = df.iloc(5[:, 2])])`

On the virtues of pragmatism

Pragmatism: *a reasonable and logical way of solving problems that is based on dealing with specific situations instead of abstract theories.*

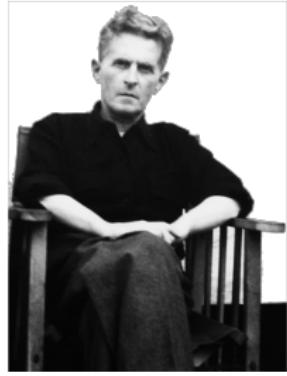

- Often framed as a compromise, “Let’s be pragmatic...”
- Pragmatism is a principled approach to problem solving.
- Taken seriously, pragmatism is difficult because it requires modeling the needs of multiple stakeholders and balancing competing interests.
- Putting it into practice requires knowing your customer, understanding their workflow, considering the most appropriate solution out of a set of possible alternatives.

“What is the use of studying philosophy if all that it does for you is to enable you to talk about some abstruse questions of logic and does not improve your thinking about the important questions of everyday life?”

Ludwig Wittgenstein, 1889–1951

On the virtues of pragmatism

- Pioneered in the 19th century by Pierce, James, Dewey, et al.
- Wittgenstein was a pragmatist, early work on language games.
- Pragmatism is a philosophy of language that emphasizes the role of intent in human communication.
- Language is a tool for communication, not just an arbitrary set of rules.
- Must actively imagine the mindset of the speaker, not just the literal meaning of their words.
- Language is a bit like a game whose goal is to understand the speaker's intent.
- Assume a proficient speaker, who is trying to communicate something meaningful.

From Error-Correcting Codes to Correcting Coding Errors

- Error-correcting codes are a well-studied topic in information theory used to detect and correct errors in data transmission.
- Introduces parity bits to detect and correct transmission errors assuming a certain noise model (e.g., Hamming distance).
- Like ECCs, we also assume a certain noise model (Levenshtein distance) and error tolerance (n -lexical tokens).
- Instead of injecting parity bits, we use the grammar and mutual information between tokens to detect and correct errors.
- Unlike ECCs, we do not assume a unique solution, but a set of admissible solutions ranked by statistical likelihood.

“Damn it, if the machine can detect an error, why can’t it locate the position of the error and correct it?””

Richard Hamming, 1915-1998

Syntax repair as a language game

- Imagine a game between two players, *Editor* and *Author*.
- They both see the same grammar, \mathcal{G} and invalid string $\underline{\sigma} \notin \mathcal{L}(\mathcal{G})$.
- Author moves by modifying $\underline{\sigma}$ to produce a valid string, $\sigma \in \mathcal{L}(\mathcal{G})$.
- Editor moves continuously, sampling a set $\tilde{\sigma} \subseteq \mathcal{L}(\mathcal{G})$.
- As soon as Author repairs $\underline{\sigma}$, the turn immediately ends.
- Neither player sees the other's move(s) before making their own.
- If Editor anticipates Author's move, i.e., $\sigma \in \tilde{\sigma}$, they both win.
- If Author surprises Editor with a valid move, i.e., $\sigma \notin \tilde{\sigma}$, Author wins.
- We may consider a refinement where Editor wins in proportion to the time taken to anticipate Author's move.

Problem Statement: Validity and naturalness

Syntax repair can be treated as a language intersection problem between a context-free language (CFL) and a regular language.

Definition (Reachable edits)

Given a CFL, ℓ , and an invalid string, $\underline{\sigma} : \ell^C$, find every valid string reachable within d edits of $\underline{\sigma}$, i.e., letting Δ be the Levenshtein metric and $L(\underline{\sigma}, d) = \{\sigma' \mid \Delta(\underline{\sigma}, \sigma') \leq d\}$ be the edit ball, we seek $A = L(\underline{\sigma}, d) \cap \ell$.

Definition (Ranked repair)

Given a finite language $A = L(\underline{\sigma}, d) \cap \ell$ and a probabilistic language model $P_\theta : \Sigma^* \rightarrow [0, 1] \subset \mathbb{R}$, the ranked repair problem is to find the top- k maximum likelihood repairs under the language model. That is,

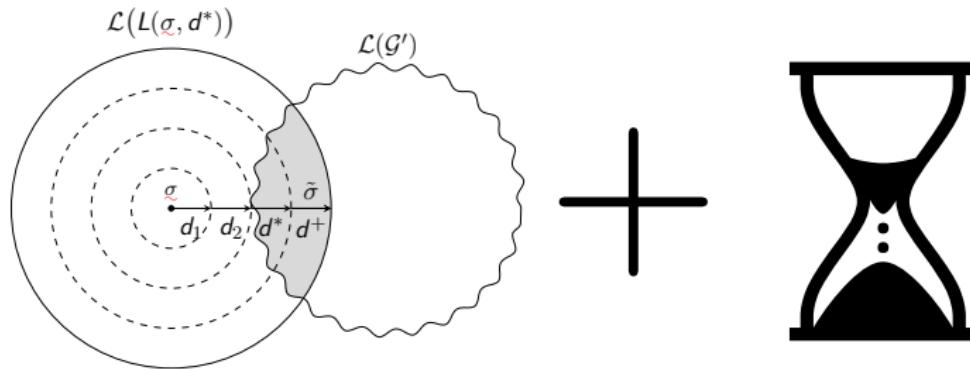

$$R(A, P_\theta) = \operatorname{argmax}_{\sigma \subseteq A, |\sigma| \leq k} \sum_{\sigma \in \sigma} P_\theta(\sigma) \quad (1)$$

Problem Statement: Temporal constraints

Find every syntactically admissible edit $\{\sigma' \in \ell \mid \Delta(\sigma, \sigma') \leq d\}$, ranked by a probability metric P_θ , and return them in a reasonable amount of time.

Definition (Linear convergence)

Given a finite CFL, ℓ , we want a generating function, $\varphi : \mathbb{N}_{<|\ell|} \rightarrow 2^\ell$, that converges linearly in expectation, i.e., $\mathbb{E}_{i \in [1, n]} |\varphi(i)| \propto n$.

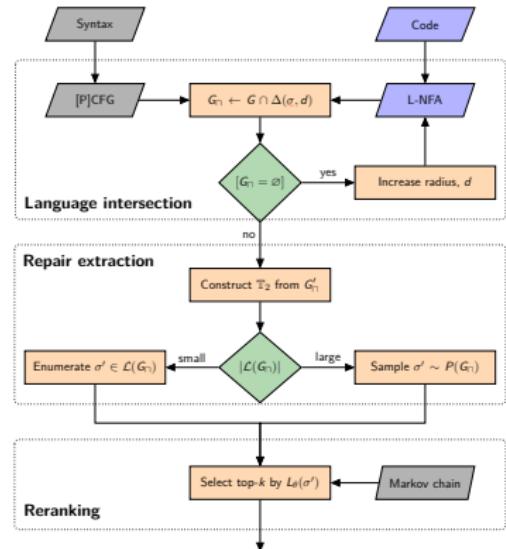

Natural language: Retrieve as many syntactically valid repairs as possible within a small neighborhood and time frame, ranked by naturalness.

High-level architecture overview

Our syntax repair procedure can be described in three high-level steps. First, we generate a synthetic grammar (G_{\cap}) representing the intersection between the syntax (G) and Levenshtein ball around the source code ($\Delta(\sigma, d)$). During repair extraction, we retrieve as many repairs as possible from the intersection grammar via sampling or enumeration. Finally, we rank all repairs discovered by likelihood.

Characteristics of the repair dataset

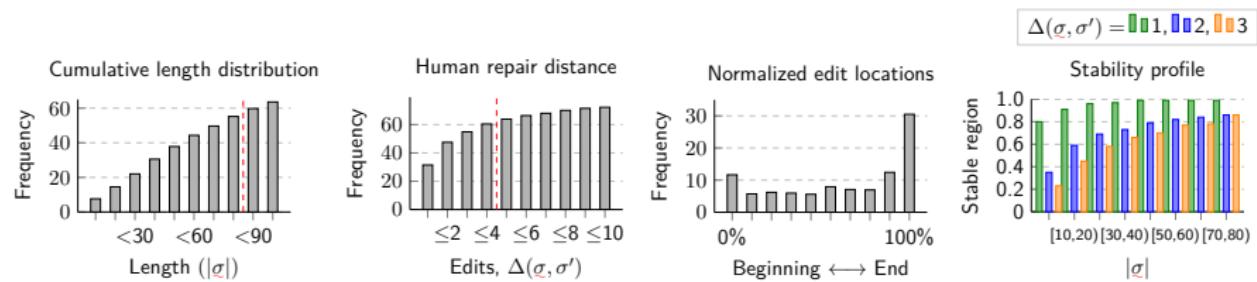

Figure: Repair statistics across the StackOverflow dataset, of which Tidyparse can handle about half in under ~ 30 s and ~ 150 GB. Larger repairs and edit distances are possible, albeit requiring additional time and memory. The stability profile measures the average fraction of all edit locations that were never altered by any repair in the $L(\sigma, \Delta(\sigma, \sigma'))$ -ball across repairs of varying length and distance.

Ranked repair

We train on lexical n-grams using the standard MLE for Markov chains.
To score the repairs, we use the conventional length-normalized NLL:

$$\text{NLL}(\sigma) = -\frac{1}{|\sigma|} \sum_{i=1}^{|\sigma|} \log P_\theta(\sigma_i \mid \sigma_{i-1} \dots \sigma_{i-n}) \quad (2)$$

For each retrieved set $\hat{A} \subseteq A$ drawn before a predetermined timeout and each $\sigma \in \hat{A}$, we score the repair and return \hat{A} in ascending order.

To evaluate the quality of our ranking, we use the Precision@k statistic. Specifically, given a repair model, $R : \Sigma^* \rightarrow 2^{\Sigma^*}$ and a parallel corpus, $\mathcal{D}_{\text{test}}$, of errors (σ^\dagger) and repairs (σ'), we define Precision@k as:

$$\text{Precision}@k(R) = \frac{1}{|\mathcal{D}_{\text{test}}|} \sum_{(\sigma^\dagger, \sigma') \in \mathcal{D}_{\text{test}}} \mathbb{1} [\sigma' \in \operatorname{argmax}_{\sigma \subset R(\sigma^\dagger), |\sigma| \leq k} \sum_{\sigma \in \sigma} \text{NLL}(\sigma)] \quad (3)$$

Precision and latency comparison

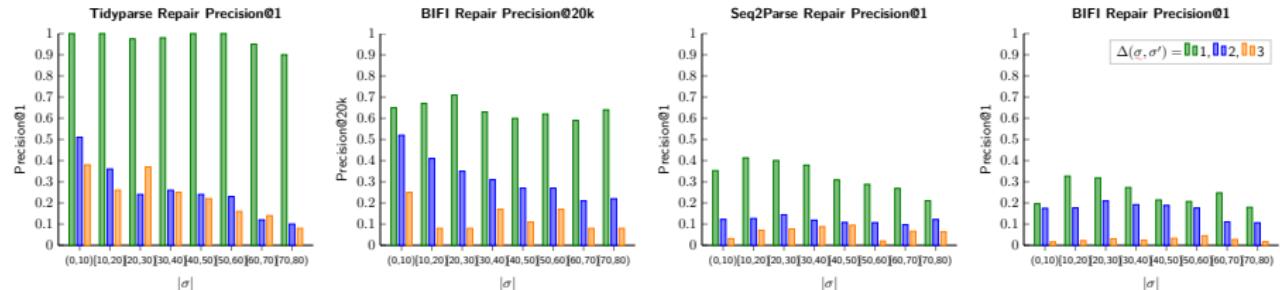

Figure: Tidyparse, Seq2Parse and BIFI repair precision across length and edits.

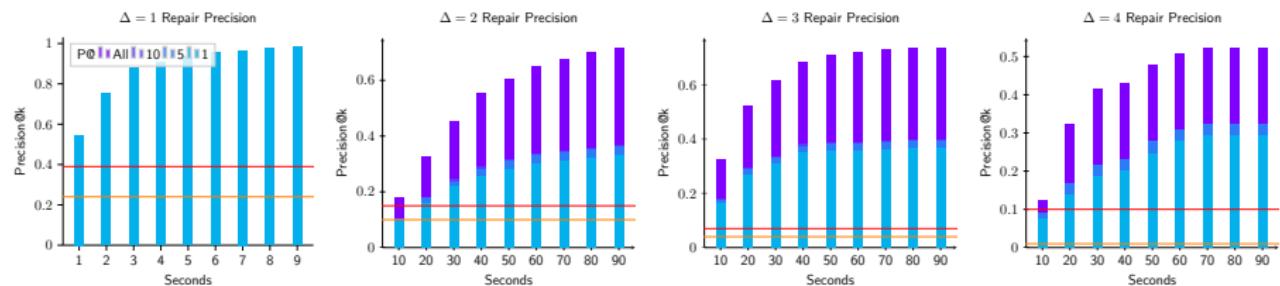

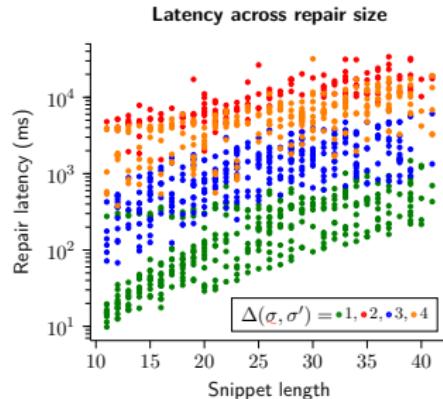

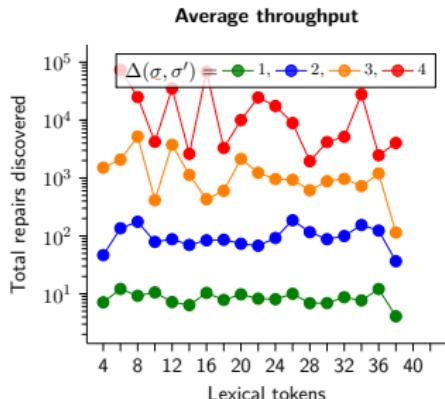

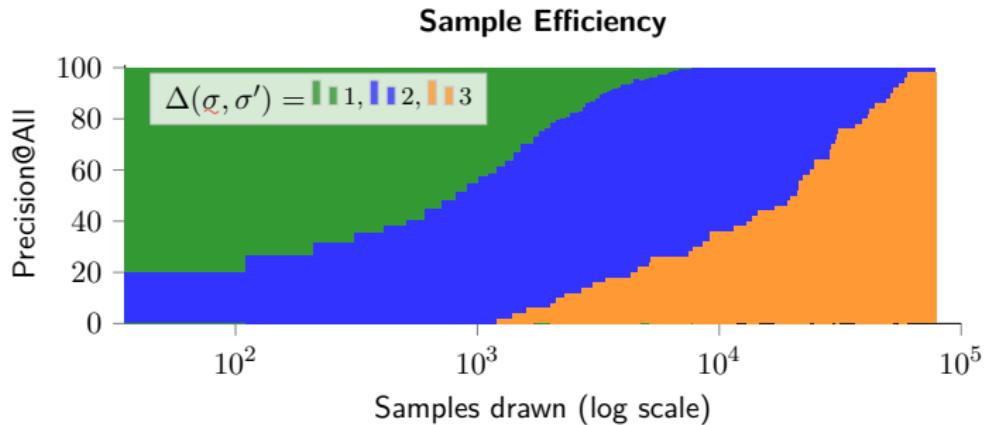

Figure: Latency benchmarks. Note the varying y-axis ranges. The red line marks Seq2Parse and the orange line marks BIFI's Precision@1 on the same repairs.

Results from sample efficiency experiments

Outcomes in the syntax repair pipeline

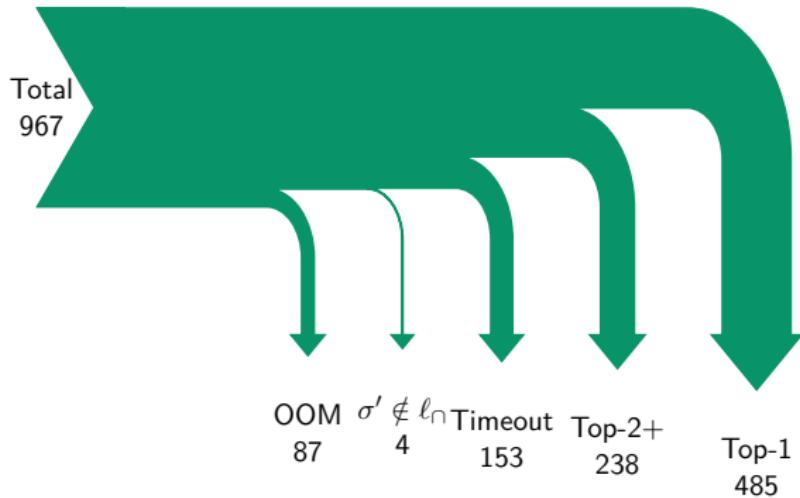

Figure: Sankey diagram of 967 total repair instances sampled uniformly from the StackOverflow Python dataset balanced across snippet lengths and edit distances ($\lfloor |\sigma|/10 \rfloor \in [0, 8]$, $\Delta(\sigma, \sigma') < 4$) with a sampling timeout of 30s per repair.

Background: Regular grammars

A regular grammar (RG) is a quadruple $\mathcal{G} = \langle V, \Sigma, P, S \rangle$ where V are nonterminals, Σ are terminals, $P : V \times (V \cup \Sigma)^{\leq 2}$ are the productions, and $S \in V$ is the start symbol, i.e., all productions are of the form $A \rightarrow a$, $A \rightarrow aB$ (right-regular), or $A \rightarrow Ba$ (left-regular). E.g., the following RG and NFA correspond to the language defined by the regex $(a(ab)^*)^*(ba)^*$:

$$S \rightarrow Q_0 \mid Q_2 \mid Q_3 \mid Q_5$$

$$Q_0 \rightarrow \varepsilon$$

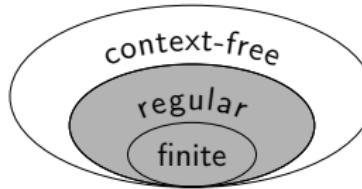

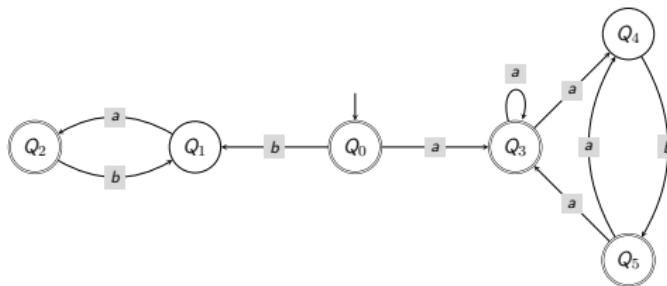

$$Q_1 \rightarrow Q_0 b \mid Q_2 b$$

$$Q_2 \rightarrow Q_1 a$$

$$Q_3 \rightarrow Q_0 a \mid Q_3 a \mid Q_5 a$$

$$Q_4 \rightarrow Q_3 a \mid Q_5 a$$

$$Q_5 \rightarrow Q_4 b$$

Levenshtein reachability

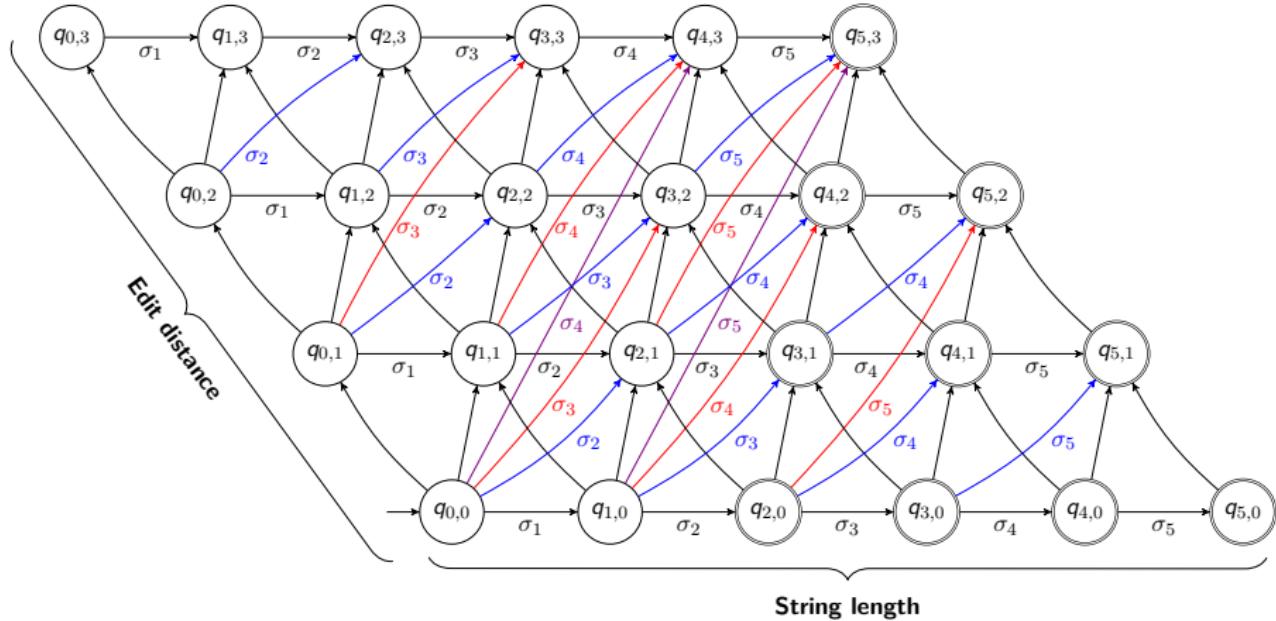

Figure: Bounded Levenshtein reachability from $\sigma : \Sigma^n$ is expressible as an NFA populated by accept states within radius k of $S = q_{n,0}$, which accepts all strings σ' within Levenshtein radius k of σ .

The nominal Levenshtein automaton

The original Levenshtein automaton (Schulz & Stoyan, 2002):

$$\begin{array}{c} \frac{s \in \Sigma \ i \in [0, n] \ j \in [1, k]}{(q_{i,j-1} \xrightarrow{s} q_{i,j}) \in \delta} \uparrow \quad \frac{s \in \Sigma \ i \in [1, n] \ j \in [1, k]}{(q_{i-1,j-1} \xrightarrow{s} q_{i,j}) \in \delta} \rightrightarrows \\ \frac{s = \sigma_i \ i \in [1, n] \ j \in [0, k]}{(q_{i-1,j} \xrightarrow{s} q_{i,j}) \in \delta} \leftrightarrow \quad \frac{s = \sigma_i \ i \in [2, n] \ j \in [1, k]}{(q_{i-2,j-1} \xrightarrow{s} q_{i,j}) \in \delta} \rightleftharpoons \\ \frac{}{q_{0,0} \in I} \text{INIT} \quad \frac{q_{i,j}}{|n - i + j| \leq k}{\frac{q_{i,j} \in F}{\text{DONE}}} \end{array}$$

We modify the original automaton with a nominal predicate:

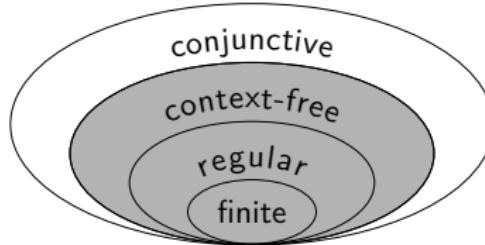

$$\begin{array}{c} \frac{i \in [0, n] \ j \in [1, k]}{(q_{i,j-1} \xrightarrow{[\neq \sigma_i]} q_{i,j}) \in \delta} \uparrow \quad \frac{i \in [1, n] \ j \in [1, k]}{(q_{i-1,j-1} \xrightarrow{[\neq \sigma_i]} q_{i,j}) \in \delta} \rightrightarrows \\ \frac{i \in [1, n] \ j \in [0, k]}{(q_{i-1,j} \xrightarrow{[=\sigma_i]} q_{i,j}) \in \delta} \leftrightarrow \quad \frac{d \in [1, d_{\max}] \ i \in [d+1, n] \ j \in [d, k]}{(q_{i-d-1,j-d} \xrightarrow{[=\sigma_i]} q_{i,j}) \in \delta} \rightleftharpoons \end{array}$$

Background: Context-free grammars

In a context-free grammar $\mathcal{G} = \langle V, \Sigma, P, S \rangle$ all productions are of the form $P : V \times (V \cup \Sigma)^+$, i.e., RHS may contain any number of nonterminals, V . Recognition decidable in n^ω , n.b. CFLs are **not** closed under intersection!

For example, consider the grammar $S \rightarrow SS \mid (S) \mid ()$. This represents the language of balanced parentheses, e.g. $(), ()(), (()), ()(()), ((())(), ((())()$...

Every CFG has a normal form $P^* : V \times (V^2 \mid \Sigma)$, i.e., every production can be refactored into either $v_0 \rightarrow v_1v_2$ or $v_0 \rightarrow \sigma$, where $v_{0..2} : V$ and $\sigma : \Sigma$, e.g., $\{S \rightarrow SS \mid (S) \mid ()\} \Leftrightarrow^* \{S \rightarrow XR \mid SS \mid LR, L \rightarrow (, R \rightarrow), X \rightarrow LS\}$

Background: Closure properties of formal languages

Formal languages are not always closed under set-theoretic operations, e.g., $\text{CFL} \cap \text{CFL}$ is not CFL in general. Let \cdot denote concatenation, $*$ be Kleene star, and \complement be complementation:

	\cup	\cap	\cdot	$*$	\complement
Finite ¹	✓	✓	✓	✓	✓
Regular ¹	✓	✓	✓	✓	✓
Context-free ^{1,2}	✓	X*	✓	✓	X
Conjunctive ^{1,2}	✓	✓	✓	✓	?
Context-sensitive ²	✓	✓	✓	+	✓
Recursively Enumerable ²	✓	✓	✓	✓	X

We would like a language family that is (1) tractable, i.e., has polynomial recognition and search complexity and (2) reasonably expressive, i.e., can represent syntactic properties of real-world programming languages.

* However, CFLs are closed under intersection with regular languages.

The Bar-Hillel construction and its specialization

The original Bar-Hillel construction provides a way to construct a grammar for the intersection of a regular and context-free language.

$$\frac{q \in I \quad r \in F}{(S \rightarrow qSr) \in P_{\cap}} \downarrow \quad \frac{(A \rightarrow a) \in P \quad (q \xrightarrow{a} r) \in \delta}{(qAr \rightarrow a) \in P_{\cap}} \uparrow$$
$$\frac{(w \rightarrow xz) \in P \quad p, q, r \in Q}{(pwr \rightarrow (pxq)(qzr)) \in P_{\cap}} \bowtie$$

We specialize the Bar-Hillel construction to nominal Levenshtein automata:

$$\frac{(A \rightarrow a) \in P \quad (q \xrightarrow{[\cdot]} r) \in \delta \quad a[\cdot]}{(qAr \rightarrow a) \in P_{\cap}} \uparrow$$
$$\frac{w \triangleleft pr \quad x \triangleleft pq \quad z \triangleleft qr \quad (w \rightarrow xz) \in P \quad p, q, r \in Q}{(pwr \rightarrow (pxq)(qzr)) \in P_{\cap}} \bowtie$$

Where \triangleleft denotes compatibility between the Parikh map of a nonterminal and Levenshtein margin between two NFA states, see our paper for details.

Parsing for linear algebraists

Given a CFG $\mathcal{G} := \langle V, \Sigma, P, S \rangle$ in Chomsky Normal Form, we can construct a recognizer $R_{\mathcal{G}} : \Sigma^n \rightarrow \mathbb{B}$ for strings $\sigma : \Sigma^n$ as follows. Let 2^V be our domain, 0 be \emptyset , \oplus be \cup , and \otimes be defined as follows:

$$s_1 \otimes s_2 := \{C \mid \langle A, B \rangle \in s_1 \times s_2, (C \rightarrow AB) \in P\}$$

e.g., $\{A \rightarrow BC, C \rightarrow AD, D \rightarrow BA\} \subseteq P \vdash \{A, B, C\} \otimes \{B, C, D\} = \{A, C\}$

If we define $\sigma_r^\uparrow := \{w \mid (w \rightarrow \sigma_r) \in P\}$, then initialize

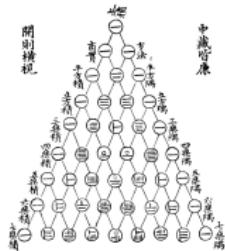

$M_{r+1=c}^0(\mathcal{G}', e) := \sigma_r^\uparrow$ and solve for the fixpoint $M^* = M + M^2$,

$$M^0 := \begin{pmatrix} \emptyset & \sigma_1^\uparrow & \emptyset & \emptyset \\ \vdots & & \emptyset & \emptyset \\ & & \emptyset & \emptyset \\ & & \sigma_n^\uparrow & \emptyset \\ \emptyset & & \emptyset & \emptyset \end{pmatrix} \Rightarrow \dots \Rightarrow M^* = \begin{pmatrix} \emptyset & \sigma_1^\uparrow & \Lambda & \Lambda_\sigma^* \\ \vdots & & \vdots & \vdots \\ & & \Lambda & \sigma_n^\uparrow \\ & & \sigma_n^\uparrow & \emptyset \\ \emptyset & & \emptyset & \emptyset \end{pmatrix}$$

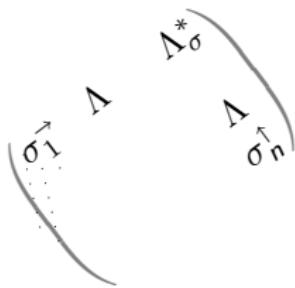

$$S \Rightarrow^* \sigma \iff \sigma \in \mathcal{L}(\mathcal{G}) \text{ iff } S \in \Lambda_\sigma^*, \text{ i.e., } \mathbb{1}_{\Lambda_\sigma^*}(S) \iff \mathbb{1}_{\mathcal{L}(\mathcal{G})}(\sigma).$$

Lattices, Matrices and Trellises

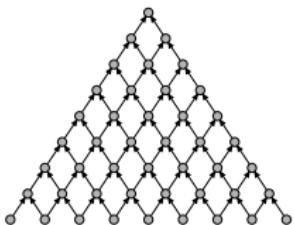

The art of treillage has been practiced from ancient through modern times.

A few observations on algebraic parsing

- The matrix \mathbf{M}^* is strictly upper triangular, i.e., nilpotent of degree n
- Recognizer can be translated into a parser by storing backpointers

$$\mathbf{M}_1 = \mathbf{M}_0 + \mathbf{M}_0^2$$

□				
	□	□ □		
		□		
		□	□ □	
				□

$$\mathbf{M}_2 = \mathbf{M}_1 + \mathbf{M}_1^2$$

□		□ □ □ □		
	□	□ □		
		□	□ □ □ □	
			□	□ □
				□

$$\mathbf{M}_3 = \mathbf{M}_2 + \mathbf{M}_2^2 = \mathbf{M}_4$$

□		□ □ □ □		□ □ □ □ □ □ □
	□	□ □		□ □ □ □ □ □ □
		□	□ □ □ □	□ □ □ □ □ □ □
			□	□ □ □ □
				□

- The \otimes operator is *not* associative: $S \otimes (S \otimes S) \neq (S \otimes S) \otimes S$
- Built-in error recovery: nonempty submatrices = parsable fragments
- `seekFixpoint { it + it * it }` is sufficient but unnecessary
- If we had a way to solve for $\mathbf{M} = \mathbf{M} + \mathbf{M}^2$ directly, power iteration would be unnecessary, could solve for $\mathbf{M} = \mathbf{M}^2$ above superdiagonal

Satisfiability + holes

- Can be lowered onto a Boolean tensor $\mathbb{B}_2^{n \times n \times |V|}$ (Valiant, 1975)
- Binarized CYK parser can be efficiently compiled to a SAT solver
- Enables sketch-based synthesis in either σ or \mathcal{G} : just use variables!
- We simply encode the characteristic function, i.e. $\mathbb{1}_{\subseteq V} : V \rightarrow \mathbb{Z}_2^{|V|}$
- \oplus, \otimes are defined as \boxplus, \boxtimes , so that the following diagram commutes:

$$\begin{array}{ccc} 2^V \times 2^V & \xrightarrow{\oplus/\otimes} & 2^V \\ \mathbb{1}^{-2} \uparrow \mathbb{1}^2 & & \mathbb{1}^{-1} \uparrow \mathbb{1} \\ \mathbb{Z}_2^{|V|} \times \mathbb{Z}_2^{|V|} & \xrightarrow{\boxplus/\boxtimes} & \mathbb{Z}_2^{|V|} \end{array}$$

- These operators can be lifted into matrices/tensors in the usual way
- In most cases, only a few nonterminals are active at any given time

Satisfiability + holes

Let us consider an example with two holes, $\sigma = 1 _ _$, and the grammar being $G := \{S \rightarrow NON, O \rightarrow + \mid \times, N \rightarrow 0 \mid 1\}$. This can be rewritten into CNF as $G' := \{S \rightarrow NL, N \rightarrow 0 \mid 1, O \rightarrow \times \mid +, L \rightarrow ON\}$. Using the algebra where $\oplus = \cup$, $X \otimes Z = \{ w \mid \langle x, z \rangle \in X \times Z, (w \rightarrow xz) \in P \}$, the fixpoint $M' = M + M^2$ can be computed as follows:

	2^V	$\mathbb{Z}_2^{ V }$	$\mathbb{Z}_2^{ V } \rightarrow \mathbb{Z}_2^{ V }$
M_0	$\begin{pmatrix} \{N\} \\ \{N, O\} \\ \{N, O\} \end{pmatrix}$	$\begin{pmatrix} \square \blacksquare \square \square \\ \square \blacksquare \blacksquare \square \\ \square \blacksquare \blacksquare \square \end{pmatrix}$	$\begin{pmatrix} V_{0,1} \\ V_{1,2} \\ V_{2,3} \end{pmatrix}$
M_1	$\begin{pmatrix} \{N\} & \emptyset & \{L\} \\ \{N, O\} & \{L\} & \{N, O\} \end{pmatrix}$	$\begin{pmatrix} \square \blacksquare \square \square & \square \square \square \square \\ \square \blacksquare \blacksquare \square & \blacksquare \square \square \square \\ \square \blacksquare \blacksquare \square \end{pmatrix}$	$\begin{pmatrix} V_{0,1} & V_{0,2} \\ V_{1,2} & V_{1,3} \\ V_{2,3} \end{pmatrix}$
M_∞	$\begin{pmatrix} \{N\} & \emptyset & \{S\} \\ \{N, O\} & \{L\} & \{N, O\} \end{pmatrix}$	$\begin{pmatrix} \square \blacksquare \square \square & \square \square \square \square & \square \square \square \blacksquare \\ \square \blacksquare \blacksquare \square & \blacksquare \square \square \square \\ \square \blacksquare \blacksquare \square \end{pmatrix}$	$\begin{pmatrix} V_{0,1} & V_{0,2} & V_{0,3} \\ V_{1,2} & V_{1,3} \\ V_{2,3} \end{pmatrix}$

Semiring algebras: Part I

The prior solution tell us whether $A(\sigma)$ is nonempty, but forgets the solution(s). To solve for $A(\sigma)$, a naïve approach accumulates a mapping of nonterminals to sets of strings. Letting $D = V \rightarrow \mathcal{P}(\Sigma^*)$, we define $\oplus, \otimes : D \times D \rightarrow D$. Initially, we construct $M_0[r + 1 = c] = p(\sigma_r)$ using:

$$p(s : \Sigma) \mapsto \{w \mid (w \rightarrow s) \in P\} \text{ and } p(_) \mapsto \bigcup_{s \in \Sigma} p(s)$$

$p(\cdot)$ constructs the superdiagonal, then we solve for Λ_σ^* using the algebra:

$$X \oplus Z \mapsto \{w \stackrel{+}{\Rightarrow} (X \circ w) \cup (Z \circ w) \mid w \in \pi_1(X \cup Z)\}$$

$$X \otimes Z \mapsto \bigoplus_{w,x,z} \{w \stackrel{+}{\Rightarrow} (X \circ x)(Z \circ z) \mid (w \rightarrow xz) \in P, x \in X, z \in Z\}$$

After M_∞ is attained, the solutions can be read off via $\Lambda_\sigma^* \circ S$. The issue here is exponential growth when eagerly computing the transitive closure.

Semiring algebras: Part II

The prior encoding can be improved using an ADT $\mathbb{T}_3 = (V \cup \Sigma) \multimap \mathbb{T}_2$ where $\mathbb{T}_2 = (V \cup \Sigma) \times (\mathbb{N} \multimap \mathbb{T}_2 \times \mathbb{T}_2)$. We construct $\hat{\sigma}_r = \dot{p}(\sigma_r)$ using:

$$\dot{p}(s : \Sigma) \mapsto \left\{ \mathbb{T}_2(w, [\langle \mathbb{T}_2(s), \mathbb{T}_2(\varepsilon) \rangle]) \mid (w \rightarrow s) \in P \right\} \text{ and } \dot{p}(_) \mapsto \bigoplus_{s \in \Sigma} p(s)$$

We then compute the fixpoint M_∞ by redefining $\oplus, \otimes : \mathbb{T}_3 \times \mathbb{T}_3 \rightarrow \mathbb{T}_3$ as:

$$X \oplus Z \mapsto \bigcup_{k \in \pi_1(X \cup Z)} \left\{ k \Rightarrow \mathbb{T}_2(k, x \cup z) \mid x \in \pi_2(X \circ k), z \in \pi_2(Z \circ k) \right\}$$

$$X \otimes Z \mapsto \bigoplus_{(w \rightarrow xz) \in P} \left\{ \mathbb{T}_2(w, [\langle X \circ x, Z \circ z \rangle]) \mid x \in \pi_1(X), z \in \pi_1(Z) \right\}$$

Semiring algebras: Part III

$$L(p) = 1 + pL(p)$$

$$P(a) = \Sigma + V + VL(V^2 P(a)^2)$$

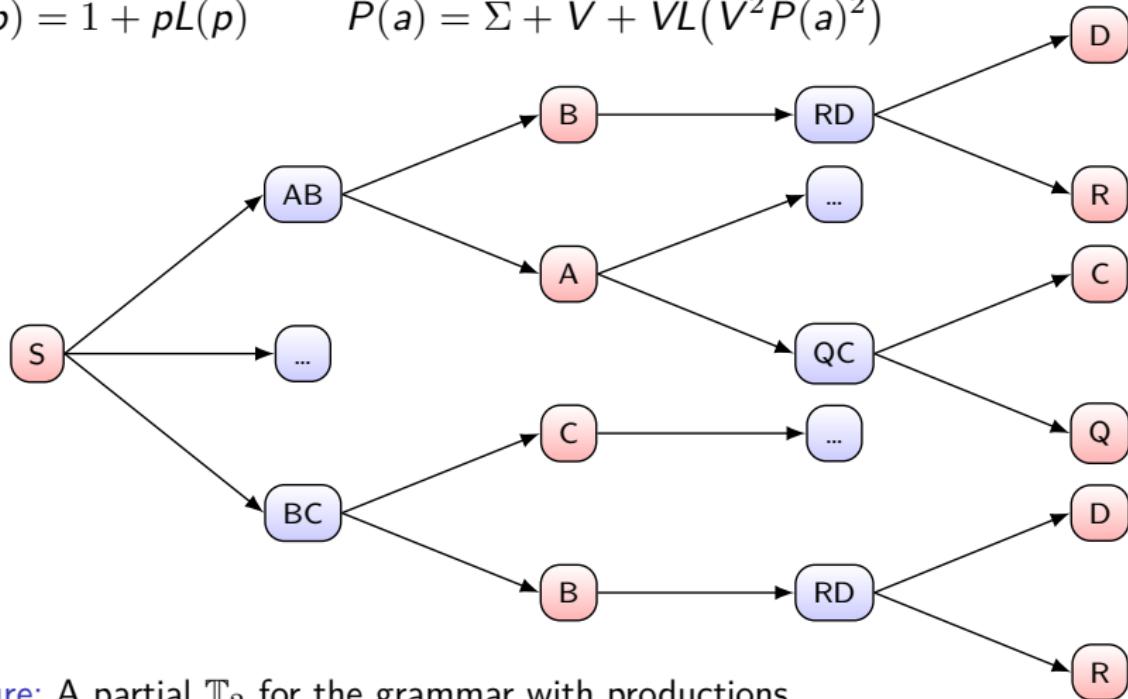

Figure: A partial \mathbb{T}_2 for the grammar with productions
 $P = \{S \rightarrow BC \mid \dots \mid AB, B \rightarrow RD \mid \dots, A \rightarrow QC \mid \dots\}$.

Sampling trees with replacement

Given a probabilistic CFG whose productions indexed by each nonterminal are decorated with a probability vector \mathbf{p} (this may be uniform in the non-probabilistic case), we define a tree sampler $\Gamma : \mathbb{T}_2 \rightsquigarrow \mathbb{T}$ which recursively samples children according to a Multinoulli distribution:

$$\Gamma(T) \mapsto \begin{cases} \text{Multi}(\text{children}(T), \mathbf{p}) & \text{if } T \text{ is a root} \\ \langle \Gamma(\pi_1(T)), \Gamma(\pi_2(T)) \rangle & \text{if } T \text{ is a child} \end{cases}$$

This is closely related to the generating function for the ordinary Boltzmann sampler from analytic combinatorics,

$$\Gamma C(x) \mapsto \begin{cases} \text{Bern} \left(\frac{A(x)}{A(x)+B(x)} \right) \rightarrow \Gamma A(x) \mid \Gamma B(x) & \text{if } \mathcal{C} = \mathcal{A} + \mathcal{B} \\ \langle \Gamma A(x), \Gamma B(x) \rangle & \text{if } \mathcal{C} = \mathcal{A} \times \mathcal{B} \end{cases}$$

however unlike Duchon et al. (2004), rejection is unnecessary to ensure exact-size sampling, as all trees in \mathbb{T}_2 will necessarily be the same size.

A pairing function for replacement-free tree sampling

The total number of trees induced by a given sketch template is given by:

$$|T : \mathbb{T}_2| \mapsto \begin{cases} 1 & \text{if } T \text{ is a leaf,} \\ \sum_{\langle T_1, T_2 \rangle \in \text{children}(T)} |T_1| \cdot |T_2| & \text{otherwise.} \end{cases}$$

To sample from \mathbb{T}_2 without replacement, we define a pairing function:

$$\varphi^{-1}(T : \mathbb{T}_2, i : \mathbb{Z}_{|T|}) \mapsto \begin{cases} \left\langle \text{BTree}(\text{root}(T)), i \right\rangle & \text{if } T \text{ is a leaf,} \\ \text{Let } b = |\text{children}(T)|, \\ q_1, r = \left\langle \lfloor \frac{i}{b} \rfloor, i \pmod{b} \right\rangle, \\ lb, rb = \text{children}[r], \\ T_1, q_2 = \varphi^{-1}(lb, q_1), \\ T_2, q_3 = \varphi^{-1}(rb, q_2) \text{ in} \\ \left\langle \text{BTree}(\text{root}(T), T_1, T_2), q_3 \right\rangle & \text{otherwise.} \end{cases}$$

Abbreviated history of algebraic parsing

- Chomsky & Schützenberger (1959) - The algebraic theory of CFLs
- Cocke–Younger–Kasami (1961) - Bottom-up matrix-based parsing
- Brzozowski (1964) - Derivatives of regular expressions
- Valiant (1975) - first realizes the Boolean matrix correspondence
 - Naïvely, has complexity $\mathcal{O}(n^4)$, can be reduced to $\mathcal{O}(n^\omega)$, $\omega < 2.763$
- Lee (1997) - Fast CFG Parsing \iff Fast BMM, formalizes reduction
- Might et al. (2011) - Parsing with derivatives (Brzozowski \Rightarrow CFL)
- Bakinova, Okhotin et al. (2010) - Formal languages over GF(2)
- Bernady & Jansson (2015) - Certifies Valiant (1975) in Agda
- Cohen & Gildea (2016) - Generalizes Valiant (1975) to parse and recognize mildly context sensitive languages, e.g. LCFRS, TAG, CCG
- **Considine, Guo & Si (2022)** - SAT + Valiant (1975) + holes
- **Considine, Guo & Si (2024)** - Levenshtein Bar-Hillel repairs

Chomsky Denormalization

Chomsky normalization is needed for matrix-based parsing, however produces lopsided parse trees. We can denormalize them using a simple recursive procedure to restore the natural shape of the original CFG:

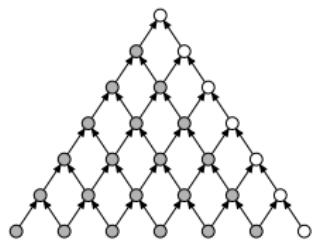

Algorithm Rewrite procedure for tree denormalization

```
procedure CUT(t: Tree)
    stems ← { CUT(c) | c ∈ t.children }
    if t.root ∈ (VG' \ VG) then
        return stems
    else
        return { Tree(t.root, stems) }
    end if
end procedure
```

All synthetic nonterminals are excised during Chomsky denormalization. Rewriting improves legibility but does not alter the underlying semantics.

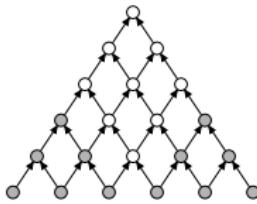

Incremental parsing

Should only need to recompute submatrices affected by individual edits. In the worst case, each edit requires quadratic complexity in terms of $|\Sigma^*|$, assuming $\mathcal{O}(1)$ cost for each CNF-nonterminal subset join, $\mathbf{V}'_1 \otimes \mathbf{V}'_2$.

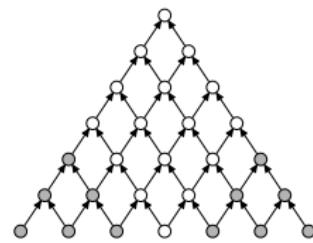

Append

$$\mathcal{O}(n + 1)$$

Delete

$$\mathcal{O}\left(\frac{1}{4}(n - 1)^2\right)$$

Insert

$$\mathcal{O}\left(\frac{1}{4}(n + 1)^2\right)$$

Related to **dynamic matrix inverse** and **incremental transitive closure** with vertex updates. With a careful encoding, we can incrementally update SAT constraints as new keystrokes are received to eliminate redundancy.

Conjunctive parsing

It is well-known that the family of CFLs is not closed under intersection.

For example, consider $\mathcal{L}_\cap := \mathcal{L}_{\mathcal{G}_1} \cap \mathcal{L}_{\mathcal{G}_2}$:

$$P_1 := \{ S \rightarrow LR, \quad L \rightarrow ab \mid aLb, \quad R \rightarrow c \mid cR \}$$
$$P_2 := \{ S \rightarrow LR, \quad R \rightarrow bc \mid bRc, \quad L \rightarrow a \mid aL \}$$

Note that \mathcal{L}_\cap generates the language $\{ a^d b^d c^d \mid d > 0 \}$, which according to the pumping lemma is not context-free. To encode \mathcal{L}_\cap , we intersect all terminals $\Sigma_\cap := \bigcap_{i=1}^c \Sigma_i$, then for each $t_\cap \in \Sigma_\cap$ and CFG, construct an equivalence class $E(t_\cap, \mathcal{G}_i) = \{ w_i \mid (w_i \rightarrow t_\cap) \in P_i \}$ as follows:

$$\bigwedge_{t \in \Sigma_\cap} \bigwedge_{j=1}^{c-1} \bigwedge_{i=1}^{|\sigma|} E(t_\cap, \mathcal{G}_j) \equiv_{\sigma_i} E(t_\cap, \mathcal{G}_{j+1}) \quad (4)$$

An Simple Reachability Proof

Lemma

For any nonempty language $\ell : \mathcal{L}(\mathcal{G})$ and invalid string $\underline{\sigma} : \Sigma^n$, there exists an $(\tilde{\sigma}, m)$ such that $\tilde{\sigma} \in \ell \cap \Sigma^m$ and $0 < \Delta(\underline{\sigma}, \ell) \leq \max(m, n) < \infty$, where Δ denotes the Levenshtein edit distance.

Proof.

Since ℓ is nonempty, it must have at least one inhabitant $\sigma \in \ell$. Let $\tilde{\sigma}$ be the smallest such member. Since $\tilde{\sigma}$ is a valid sentence in ℓ , by definition it must be that $|\tilde{\sigma}| < \infty$. Let $m := |\tilde{\sigma}|$. Since we know $\underline{\sigma} \notin \ell$, it follows that $0 < \Delta(\underline{\sigma}, \ell)$. Let us consider two cases, either $\tilde{\sigma} = \varepsilon$, or $0 < |\tilde{\sigma}|$:

- If $\tilde{\sigma} = \varepsilon$, then $\Delta(\underline{\sigma}, \tilde{\sigma}) = n$ by full erasure of $\underline{\sigma}$, or
- If $0 < m$, then $\Delta(\underline{\sigma}, \tilde{\sigma}) \leq \max(m, n)$ by overwriting.

In either case, it follows $\Delta(\underline{\sigma}, \ell) \leq \max(m, n)$ and ℓ is always reachable via a finite nonempty set of Levenshtein edits, i.e., $0 < \Delta(\underline{\sigma}, \ell) < \infty$. □

Probabilistic repair generation

Algorithm Probabilistic reachability with adaptive resampling

Require: \mathcal{G} grammar, $\underline{\sigma}$ broken string, p process ID, c total CPU cores, t_{total} timeout.

```
1:  $\mathcal{Q} \leftarrow \emptyset, \mathcal{R} \leftarrow \emptyset, \epsilon \leftarrow 1, i \leftarrow 0, Y \sim \mathbb{Z}_2^m, t_0 \leftarrow t_{\text{now}}$            ▷ Initialize replay buffer  $\mathcal{Q}$  and reservoir  $\mathcal{R}$ .
2: repeat
3:   if  $\mathcal{Q} = \emptyset$  or Rand(0, 1)  $< \epsilon$  then
4:      $\hat{\sigma} \leftarrow \varphi^{-1}((\kappa, \rho)^{-1}(U^{ci+p}Y), \underline{\sigma}), i \leftarrow i + 1$           ▷ Sample WoR using the leapfrog method.
5:   else
6:      $\hat{\sigma} \sim \mathcal{Q} + \mathbf{Noise}(\mathcal{Q})$                                               ▷ Sample replay buffer with additive noise.
7:   end if
8:    $\mathcal{R} \leftarrow \mathcal{R} \cup \{\hat{\sigma}\}$                                          ▷ Insert repair candidate  $\hat{\sigma}$  into reservoir  $\mathcal{R}$ .
9:   if  $\mathcal{R}$  is full then
10:     $\hat{\sigma} \leftarrow \operatorname{argmin}_{\hat{\sigma} \in \mathcal{R}} PP(\hat{\sigma})$                       ▷ Select lowest perplexity repair candidate.
11:    if  $\hat{\sigma} \in \mathcal{L}(\mathcal{G})$  then
12:       $\mathcal{Q} \leftarrow \mathcal{Q} \cup \{\hat{\sigma}\}$                                          ▷ Insert successful repair into replay buffer.
13:    end if
14:     $\mathcal{R} \leftarrow \mathcal{R} \setminus \{\hat{\sigma}\}$                                          ▷ Remove checked sample from the reservoir.
15:  end if
16:   $\epsilon \leftarrow \mathbf{Schedule}((t_{\text{now}} - t_0)/t_{\text{total}})$                          ▷ Update exploration/exploitation rate.
17: until  $t_{\text{total}}$  elapses.
18: return  $\tilde{\sigma} \in \mathcal{Q}$  ranked by  $PP(\tilde{\sigma})$ .
```
